

Spartan App - One Page Summary

Repo evidence snapshot - generated 2026-03-04

What it is

Spartan is an Expo React Native fitness app that combines workout logging, social interaction, and progress tracking in one mobile experience.

It uses Firebase Auth, Firestore, Storage, and Cloud Functions as its primary backend platform.

Who it is for

Primary persona: lifters training with friends or small teams who want accountability through shared workouts, leaderboards, and daily nutrition tracking.

What it does

- Tracks active workouts with exercise selection, sets, templates, and rest timer flows (frontend/components/3_Workout/*).
- Supports feed posts with media, likes, comments, and workout attachments (backend/posts/createPost.js and related post modules).
- Provides direct/group chat with reactions and image media sharing (frontend/screens/1.1_Messages.js and backend/messages/sendMessageV2.js).
- Logs macros and meals by day, including barcode-assisted nutrition lookups (frontend/screens/MacroTracking.js and functions/index.js FatSecret callables).
- Runs competition views for ladder, progress, and leaderboards with rank and hexagon stats (frontend/screens/2_Competition.js and functions/index.js).
- Handles social/chat notifications through callable and trigger functions plus client listeners (functions/index.js and frontend/state/notificationsStore.js).

How it works (repo-backed architecture)

- Client UI: App.js boots a root stack and tab shell (Feed, MacroTracking, Competition, Profile) backed by frontend/screens/*.
- Client service layer: backend/*, frontend/services/*, and frontend/logic/* orchestrate Firestore/Storage reads and writes for user, post, workout, and message data.
- Backend services: functions/index.js provides callable APIs, Firestore triggers, and scheduled jobs (for example leaderboard rank refresh).
- Data flow: UI action -> client module read/write or callable function -> Firestore security rules check (firestore.rules) -> snapshots update app state.

How to run (minimal)

- Install dependencies at repo root: npm install.
- Set optional OAuth values in .env.example if Google sign-in is needed.
- Start Expo dev server: npm run start.
- Launch a platform build: npm run ios or npm run android.
- Cloud Functions emulator/start command and full local Firebase setup guide: Not found in repo.
